- ▶ PHP Variable Scope
- ▶ PHP Operators
- ▶ Conditional Statements
- ▶ PHP Arrays

What is PHP

- ▶ PHP is a powerful tool for making dynamic and interactive Web pages.
- ▶ PHP stands for **PHP: Hypertext Preprocessor**
- ▶ PHP is a server-side scripting language, like ASP
- ▶ PHP scripts are executed on the server
- ▶ PHP supports many databases (MySQL, Informix, Oracle, Sybase, Solid, PostgreSQL, Generic ODBC, etc.)
- ▶ PHP is an open source software, free to download and use.

What is PHP file

- ▶ PHP files can contain text, HTML tags and scripts
- ▶ PHP files are returned to the browser as plain HTML
- ▶ PHP files have a file extension of ".php", ".php3", or ".phtml"

What is MySQL

- ▶ MySQL is a database server
- ▶ MySQL is ideal for both small and large applications
- ▶ MySQL supports standard SQL
- ▶ MySQL compiles on a number of platforms
- ▶ MySQL is free to download and use

PHP + MySQL

- ▶ PHP combined with MySQL are cross-platform (you can develop in Windows and serve on a Unix platform)
- ▶ PHP runs on different platforms (Windows, Linux, Unix, etc.)
- ▶ PHP is compatible with almost all servers used today (Apache, IIS, etc.)
- ▶ PHP is FREE to download from the official PHP resource: www.php.net
- ▶ PHP is easy to learn and runs efficiently on the server side

Download PHP, MySQL, Apache Server

- ▶ Download PHP for free here: <http://www.php.net/downloads.php>
- ▶ Download MySQL for free here: <http://www.mysql.com/downloads/>
- ▶ Download Apache for free here: <http://httpd.apache.org/download.cgi>

PHP Syntax

- ▶ A PHP script always starts with `<?php` and ends with `?>`. A PHP script can be placed anywhere in the document.
- ▶ On servers with shorthand-support, you can start a PHP script with `<?` and end with `?>`.
- ▶ For maximum compatibility, recommended to use the standard form (`<?php`) rather than the shorthand form.
- ▶ A PHP file must have a `.php` extension.
- ▶ A PHP file normally contains HTML tags, and some PHP scripting code.

- ▶

```
<html>
<body>
<?php
echo "Hello World";
?>
</body>
</html>
```

- ▶ There are two basic statements to output text with PHP: **echo** and **print**.

PHP Variables

Rules for PHP variable names:

- ▶ Variables in PHP starts with a \$ sign, followed by the name of the variable
- ▶ The variable name must begin with a letter or the underscore character
- ▶ A variable name can only contain alpha-numeric characters and underscores (A-z, 0-9, and _)
- ▶ A variable name should not contain spaces
- ▶ Variable names are case sensitive (y and Y are two different variables)

Creating (Declaring) PHP Variables

- ▶ `$myCar="Volvo";`
- ▶ After the execution of the statement above, the variable `myCar` will hold the value **Volvo**.

PHP Variable Scope

- ▶ PHP has four different variable scopes:
 - ▶ local
 - ▶ global
 - ▶ static
 - ▶ parameter

Local Scope

- ▶ A variable declared **within** a PHP function is local and can only be accessed within that function.

```
<?php
$a = 5; // global scope

function myTest()
{
    echo $a; // local scope
}

myTest();
?>
```

- ▶ The script above will not produce any output because the echo statement refers to the local scope variable `$a`, which has not been assigned a value within this scope.

Global Scope

- ▶ Global scope refers to any variable that is defined outside of any function.
- ▶ Global variables can be accessed from any part of the script that is not inside a function.
- ▶ To access a global variable from within a function, use the **global** keyword.

```
<?php
$a = 5;
$b = 10;

function myTest ()
{
    global $a, $b;
    $b = $a + $b;
}

myTest ();
echo $b;
?>
```

- ▶ The script above will output 15.

Static Scope

- ▶ When a function is completed, all of its variables are normally deleted. However, sometimes you want a local variable to not be deleted.
- ▶ To do this, use the **static** keyword when you first declare the variable.

example: `static $rememberMe;`

Parameters

- ▶ A parameter is a local variable whose value is passed to the function by the calling code.
- ▶ Parameters are declared in a parameter list as part of the function declaration

```
function myTest($para1,$para2,...)
{
// function code
}
```

- ▶ Parameters are also called arguments.

PHP String Variables

- ▶ A string variable is used to store and manipulate text.

```
<?php  
$txt="Hello World";  
echo $txt;  
?>
```

- ▶ The output of the code above will be:
Hello World

The Concatenation Operator

- ▶ The concatenation operator (.) is used to put two string values together.
- ▶ To concatenate two string variables together, use the concatenation operator:

```
<?php
$txt1="Hello World!";
$txt2="What a nice day!";
echo $txt1 . " " . $txt2;
?>
```

- ▶ The output of the code above will be:
Hello World! What a nice day!

The strlen() function

- ▶ The strlen() function is used to return the length of a string.

```
<?php  
echo strlen("Hello world!");  
?>
```

- ▶ The output of the code above will be:
12.

PHP Operators

- ▶ The assignment operator = is used to assign values to variables in PHP.
- ▶ The arithmetic operator + is used to add values together.

Arithmetic Operators

Operator	Name	Description	Example	Result
$x + y$	Addition	Sum of x and y	$2 + 2$	4
$x - y$	Subtraction	Difference of x and y	$5 - 2$	3
$x * y$	Multiplication	Product of x and y	$5 * 2$	10
x / y	Division	Quotient of x and y	$15 / 5$	3
$x \% y$	Modulus	Remainder of x divided by y	$5 \% 2$ $10 \% 8$ $10 \% 2$	1 2 0
- x	Negation	Opposite of x	- 2	
a . b	Concatenation	Concatenate two strings	"Hi" . "Ha"	HiHa

► Assignment Operators

Assignment	Same as...	Description
<code>x = y</code>	<code>x = y</code>	The left operand gets set to the value of the expression on the right
<code>x += y</code>	<code>x = x + y</code>	Addition
<code>x -= y</code>	<code>x = x - y</code>	Subtraction
<code>x *= y</code>	<code>x = x * y</code>	Multiplication
<code>x /= y</code>	<code>x = x / y</code>	Division
<code>x %= y</code>	<code>x = x % y</code>	Modulus
<code>a .= b</code>	<code>a = a . b</code>	Concatenate two strings

Operator	Name	Description
<code>++ x</code>	Pre-increment	Increments x by one, then returns x
<code>x ++</code>	Post-increment	Returns x, then increments x by one
<code>-- x</code>	Pre-decrement	Decrements x by one, then returns x
<code>x --</code>	Post-decrement	Returns x, then decrements x by one

Comparison Operators

- ▶ Comparison operators allows you to compare two values

Operator	Name	Description	Example
<code>x == y</code>	Equal	True if x is equal to y	<code>5==8</code> returns false
<code>x === y</code>	Identical	True if x is equal to y, and they are of same type	<code>5==="5"</code> returns false
<code>x != y</code>	Not equal	True if x is not equal to y	<code>5!=8</code> returns true
<code>x <> y</code>	Not equal	True if x is not equal to y	<code>5<>8</code> returns true
<code>x !== y</code>	Not identical	True if x is not equal to y, or they are not of same type	<code>5!== "5"</code> returns true
<code>x > y</code>	Greater than	True if x is greater than y	<code>5>8</code> returns false
<code>x < y</code>	Less than	True if x is less than y	<code>5<8</code> returns true
<code>x >= y</code>	Greater than or equal to	True if x is greater than or equal to y	<code>5>=8</code> returns false
<code>x <= y</code>	Less than or equal to	True if x is less than or equal to y	<code>5<=8</code> returns true

Logical Operators

Operator	Name	Description	Example
x and y	And	True if both x and y are true	x=6 y=3 (x < 10 and y > 1) returns true
x or y	Or	True if either or both x and y are true	x=6 y=3 (x==6 or y==5) returns true
x xor y	Xor	True if either x or y is true, but not both	x=6 y=3 (x==6 xor y==3) returns false
x && y	And	True if both x and y are true	x=6 y=3 (x < 10 && y > 1) returns true
x y	Or	True if either or both x and y are true	x=6 y=3 (x==5 y==5) returns false
! x	Not	True if x is not true	x=6 y=3 !(x==y) returns true

Array Operators

Operator	Name	Description
$x + y$	Union	Union of x and y
$x == y$	Equality	True if x and y have the same key/value pairs
$x === y$	Identity	True if x and y have the same key/value pairs in the same order and of the same types
$x != y$	Inequality	True if x is not equal to y
$x <> y$	Inequality	True if x is not equal to y
$x !== y$	Non-identity	True if x is not identical to y

Conditional Statements

In PHP we have the following conditional statements:

- ▶ **if statement** - use this statement to execute some code only if a specified condition is true
- ▶ **if...else statement** - use this statement to execute some code if a condition is true and another code if the condition is false
- ▶ **if...elseif....else statement** - use this statement to select one of several blocks of code to be executed
- ▶ **switch statement** - use this statement to select one of many blocks of code to be executed

▶ The if Statement

▶ Use the if statement to execute some code only if a specified condition is true.

▶ Syntax:

if (condition) code to be executed if condition is true;

▶ will output "Have a nice weekend!" if the current day is Friday

```
<html>
<body>

<?php
$d=date("D");
if ($d=="Fri") echo "Have a nice weekend!";
?>

</body>
</html>
```

- ▶ Use **break** to prevent the code from running into the next case automatically. The default statement is used if no match is found.

```
<html>
<body>

<?php
$x=1;
switch ($x)
{
case 1:
    echo "Number 1";
    break;
case 2:
    echo "Number 2";
    break;
case 3:
    echo "Number 3";
    break;
default:
    echo "No number between 1 and 3";
}
?>

</body>
</html>
```

PHP Switch Statement

- ▶ Conditional statements are used to perform different actions based on different conditions.
- ▶ Use the switch statement to select one of many blocks of code to be executed.

```
switch (n)
{
case label1:
    code to be executed if n=label1;
    break;
case label2:
    code to be executed if n=label2;
    break;
default:
    code to be executed if n is different from both label1 and label2;
}
```

PHP Arrays

- ▶ An array is a special variable, which can store multiple values in one single variable.

```
$cars1="Saab";  
$cars2="Volvo";  
$cars3="BMW";
```

▶ **There are three kind of arrays:**

- ▶ **Numeric array** - An array with a numeric index
- ▶ **Associative array** - An array where each ID key is associated with a value
- ▶ **Multidimensional array** - An array containing one or more arrays

Numeric Arrays

- ▶ A numeric array stores each array element with a numeric index.
- ▶ There are two methods to create a numeric array.

- ▶ the index are automatically assigned (the index starts at 0).

```
$cars=array("Saab","Volvo","BMW","Toyota");
```

- ▶ assign the index manually.

```
$cars[0]="Saab";  
$cars[1]="Volvo";  
$cars[2]="BMW";  
$cars[3]="Toyota";
```

- ▶ Example: access the variable values by referring to the array name and index.

```
$cars[0]="Saab";  
$cars[1]="Volvo";  
$cars[2]="BMW";  
$cars[3]="Toyota";
```

- ▶ Output:
Saab and Volvo are Swedish cars.

Associative Arrays

- ▶ An associative array, each ID key is associated with a value.
- ▶ Example 1: an array to assign ages to the different persons.
`$ages = array("Peter"=>32, "Quagmire"=>30, "Joe"=>34);`
- ▶ Example 2: shows a different way of creating the array.
`$ages['Peter'] = "32";`
`$ages['Quagmire'] = "30";`
`$ages['Joe'] = "34";`

- ▶ The ID keys can be used in a script.

```
<?php
$ages['Peter'] = "32";
$ages['Quagmire'] = "30";
$ages['Joe'] = "34";

echo "Peter is " . $ages['Peter'] . " years old.";
?>
```

- ▶ Output: Peter is 32 years old.

Latihan Soal

- ▶ Buat script php untuk menampilkan informasi dosen wali yang meliputi kondisi berikut:
 - ▶ Dosen Wali NRP 01 - 15 : M. Udin Harun AlRasyid
 - ▶ Tanggal Perwalian: 1-7 Maret 2018
 - ▶ Dosen Wali NRP 16 - 30 : Desy Intan Permatasari
 - ▶ Tanggal Perwalian: 8-15 Maret 2018
- ▶ Nama yang harus tersimpan di variable adalah:
 - ▶ NRP
 - ▶ Dosen Wali
 - ▶ Tanggal Perwalian

Finish
